

# **Scripts Execution**

# Screenshots of the execution of the scripts written

This document begins its explanation after loading data from RDS & CSV. Here I'll explain about logic that does relevant analysis as per the rules and feeds the data in the look-up table.

Member\_score table:

At first, join CARD\_MEMBER & MEMBER\_SCORE tables to extract and absord credit score of each member.

Extract required fields from merged dataset i.e. member ID, credit score and card\_id.

Next, join both history transaction CSV with score DF which is a merged and extracted data frame from both RDS tables.

```
In [40]: hist = tranf.join(score, tranf.member_id == score.mem_id,how='outer')
In [41]: hist.count()
Out[41]: 53210
    In [43]: hist = hist.select('card_id', 'amount', 'postcode', 'pos_id', 'transaction_dt', 'status', 'score')
    In [44]: hist.show()

```

Join previous last step data frame (score) with look\_up\_table dataset created above. This step frames all required cols for look\_up\_table except the UCL.

## Calculating UCL:

To calculate UCL, we will need to play upon amount field.

Its given in our module that UCL = Moving Average + 3 \* (Standard Deviation)

We will first calculate moving average of card amount's for last 10 transactions.

For this, as a first step, we create a window over which we group dataframe on card\_id such that transactions on same card\_id collate and then order them on transaction-date.

Which means we figure out all card transactions grouped by card on chronological order. Rank each of these row from 1 being latest and 2 being next latest.

Choose only rows whose rank is less than 10, thus only taking top 10 transactions on each card\_id.

```
In [67]: window = Window.partitionBy(history['card_id']).orderBy(history['transaction_date'].desc())
         history_df = history.select('*', f.rank().over(window).alias('rank')).filter(f.col('rank') <= 10)
In [68]: history_df.show()
         +-----

```

Import SQL function library on pyspark and calculate average of these 10 rows. This gives you moving average.

Stddev on amount field should give you standard deviation on 10 rows taken.

Now apply formula of UCL i.e. moving average + 3 \* (standard deviation) on above derivations and your UCL should be ready.

```
In [69]: history_df = history_df.groupBy("card_id").agg(f.round(f.avg('amount'),2).alias('moving_avg'), \
                                                                                               f.round(f.stddev('amount'),2).alias('Std_Dev'))
           history_df.show()

```

Drop duplicates on this DF to remove redundant transactions done of card\_id, transaction date, score & post code.

```
In [74]: look_up_table = look_up_table.dropDuplicates((['card_id','transaction_date','postcode']))
In [75]: look_up_table.count()
Out[75]: 1000
```

Loading Dataframe to look up table:

We take help of our good friend happybase API to perform this task for us.

Taking reference of batch loading of data into NoSQL(Hbase) taught in upgrad modules shall allow us to write bulk data into Hbase tables.

Process involved in creating & loading data into tables:

- 1) Creating connection with hbase
- 2) Checking if table already exists
- 3) Create table as desired if table doesn't already exist.
- 4) Batch insert data into table created in step 3 from final dataframe created above.

#### Step 1:

### Step 2:

```
In [78]: #create the required table
def create_table(name,cf):
    print "creating table " + name
    tables = list_tables()
    if name not in tables:
        open_connection()
        connection.create_table(name, cf)
        close_connection()
        print "table created"
    else:
        print "table already present"
    #get the pointer to a table
    def get_table(name):
        open_connection()
        table = connection.table(name)
        close_connection()
        return table
```

# Step 3:

# Step 4:

```
In [85]: #batch insert data in lookup table
        def batch_insert_data(df,tableName):
         print "starting batch insert of events"
         table = get_table(tableName)
open_connection()
         rows_count=0
        \#Creating\ a\ rowkey\ for\ better\ data\ query.\ RowKey\ is\ the\ cardId\ .
         rowKey_dict={}
         with table.batch(batch_size=4) as b:
           for row in df.rdd.collect():
           'info:score':bytes(row.score),
                               'info:postcode':bytes(row.postcode),
                              'info:UCL':bytes(row.UCL)})
         print "batch insert done"
         close_connection()
In [86]: batch_insert_data(look_up_table,'look_up_table')
        starting batch insert of events
                                                                                                             Activate Windows
        batch insert done
```

Once execution is complete, login to putty as root and enter Hbase shell

Give command 'list' to see existing tables.

```
hbase(main):001:0> list

TABLE
card_transactions
employee
look_up_table
3 row(s) in 0.3340 seconds

=> ["card_transactions", "employee", "look_up_table"]
```

Scan 'look up table' to see content inside look up table created in pyspark file.
